A LMER was used to model the relationship between group performance expectation violations and group click. Group Performance Expectations, Condition, and their interaction were included as fixed effects, and experiment session was modelled as a random effect (intercept and slope). To control for perceptions of individual performance relative to prior expectations, post-Experiment arousal, the average performance outcome of each invasion drill trial, and subjective and objective measures of athlete technical competence, these factors were included as fixed effects.

The model revealed a significant positive main effect of group performance expectation violation on feelings of team click with the training group, $\beta =$
